

PROSTHESIS SOCKET DIRECT CASTING DEVICE HAVING MULTIPLE COMPRESSION CHAMBERS

5 This application claims the benefit of Provisional Patent Application
Serial No. 60/416,589 filed October 8, 2002.

BACKGROUND OF THE INVENTION

1. Field of the Invention

10 This invention relates to a casting device for directly forming or casing
prosthesis sockets on residual limbs. More particularly, the invention relates
to a casting device that may be placed directly on a residuum to pressurize a
moldable and settable prosthesis socket material previously applied over the
15 residuum to thereby produce a socket a finished internal volume.

2. Background of Related Art

Residual limb prosthesis hard sockets have been formed using various
techniques, including plaster of paris molds, computer modeling, vacuum
20 forming and various other techniques known to prosthetists. A prior art
technique is also known where a prosthesis socket is directly cast on a
residuum using a portable pressure casting system, this system being
described in U.S. Patent No. 5,718,925. This technique enables direct
pressure casting of a prosthesis socket on a residual limb while tension is
25 applied to the distal area of the residual limb to thereby produce a definitive
socket requiring minimum finishing and adjustment upon completion of the
casting procedure.

Another version of a direct pressure casting system is described in U.S.
Patent No. 5,885,509, whereby a portable annular pressure casting bladder
30 is rolled over a residuum with a settable socket material thereon and the
prosthesis socket is molded and hardened under pressure on the residuum
while the residuum is tensioned and elongated during the molding process.

It has been observed that such procedures known in the prior art can
be improved to provide better control over distribution of casting pressure
35 during the prosthesis socket molding procedure to yield an improved
prosthesis socket having a better fit on the residuum upon completion of the
molding procedure.

The present invention is intended to provide an improvement over known prior art systems and in particular, over direct casting systems using a single annular bladder for compressing prosthesis socket material on a residuum during a molding procedure.

5

BRIEF SUMMARY OF THE INVENTION

The present invention is a prosthesis socket casting device of the type described in U.S. Patent No. 5,885,509 which is incorporated herein in its entirety by reference. More specifically, the present invention is a portable prosthesis direct casting device, including a base on which is mounted an elongated pliable annular molding bladder having a plurality of expandable chambers that peripherally surround a centrally located casting area. The bladder may be rolled back toward the base or forwardly of the base to permit a residuum to be located in the casting area within the bladder with its associated expandable chambers enveloping the residuum.

The chambers are made of a pliable, fluid impermeable, thin sheet material that, when expanded by internal pressure, flex inwardly towards the central casting area to pressurize a residuum in the casting area with a prosthesis socket material already applied to the external distal area of the residuum. The expandable chambers may be individually or collectively pressurized in a manner to produce inwardly directed forces about the periphery of the residuum and its associated socket casting material during molding and setting (curing) of the socket material. The chambers may include a radially inward facing wall made of elasticized thin sheet material.

In the manner described in U.S. Patent No. 5,885,509, a suction socket typically formed of silicone or the like, is placed on the residuum before application of the prosthetic socket molding material, with a locking pin installed on the suction sleeve extending distally from the distal end of the suction sleeve. The locking pin cooperates with the base to secure the distal end of the suction sleeve against movement relative to the base or in a manner whereby the pin may be pulled axially in a distal direction to elongate

the suction sleeve and the distal end area of the residuum during molding of the prosthetic socket material under pressure from the expandable chambers.

5 The base includes a lock device for engaging the locking pin and securing same relative to the base or relative to a traction device capable of exerting a tractile force on the locking pin in a distal direction relative to the bladder and its associated expandable chambers.

10 The base includes appropriate conduits and valves for enabling transmittal of pressurized air or other fluid into the interiors of the expandable chambers to cause their expansion inwardly toward the central casting area during a molding (casting) procedure.

15 The configuration and orientation of the multiple expandable chambers is selected to provide desired pressure distribution over the prosthesis socket material being molded to a residuum to thereby ensure a proper fit of the molded and hardened socket on the residuum with little or no adjustment required by the prosthetist.

20 In a preferred embodiment, three longitudinally extending, circumferentially spaced expandable chambers are provided on the interior of the bladder. In an alternate embodiment, a plurality of internal, longitudinally extending, circumferentially spaced expandable chambers may be surrounded by a single annular expandable bladder, with each one or groups of the bladders pressurizable independently of each other or with all bladders in fluid communication with each other.

25 The bladder preferably includes an outer fabric covering, for example, an elasticized fabric, that controls outward distention of the outer wall of the bladder when the expandable chambers are pressurized. This ensures that the force of the expandable chambers is directed inwardly toward the casting area and not outwardly away from the casting area.

30 A hand pump may be associated with the casting device in the manner disclosed in U.S. Patent No. 5,885,509.

20 Fig. 7 is a perspective view showing the prosthetic socket casting device of Fig. 1 after separation from a prosthesis socket and residuum upon completion of a casting procedure.

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS OF THE INVENTION

25 With reference to Figs. 1 and 2, a prosthesis socket casting device 10 includes a base member 12 which incorporates a lock device 16 that cooperates with a locking pin 28 having a threaded end 30 connectable with the distal end of a suction sleeve 62 (see Fig. 7) donned on a residuum before the casting device is placed in a casting position.

30 The suction socket is described in U.S. Patent No. 5,718,925 and 5,885,509 and typically comprises a highly pliable silicone elastomer socket having an end structure that includes a threaded socket for receiving the

threaded end 30 of a locking pin of the type shown at 28. Suction sockets are used to connect a hard prosthesis socket with a residuum through a vacuum connection and typically are connected with a socket by a locking pin such as pin 28. A suction socket is utilized with the present invention to provide a
5 covering for the residuum over which the prosthesis socket molding material is applied so that the suction socket provides a spacer between the residuum and the finished prosthesis socket that results in production of a correct internal volume within the prosthesis socket that allows for the volume of the suction socket when the prosthesis socket is worn by the amputee with a
10 suction sleeve.

In addition, as disclosed in Patent No. 5,885,509, use of the suction socket over the residuum and under the prosthesis socket casting material enables a locking pin 28 to be secured to the distal end of the suction socket and to be connected to the base 12 of the casting device 10. Securing the
15 locking pin to the base 12 results in a tractive force being applied to the distal end of the residuum during casting, as described in Patent No. 5,885,509 and to be discussed in more detail below.

In accordance with the embodiment of the invention shown in Figs. 1 and 2, the pin 28 may be secured against axial movement relative to a
20 connector 14 which releasably engages the pin 28 to secure the pin against movement in a proximal direction relative to the base 12. The connector 14 may be rigidly secured to the base 12 if desired or, optionally, may be associated with a pulling handle 22 that may be manipulated by a prosthetist to pull pin 28 in a distal direction during use of the casting device 10.

25 In accordance with this example, upon connection of pin 28 via end 30 to a suction socket that has been placed over a residuum, and assuming that the base 12, and bladder 34 (to be described below) remain located relative to a residuum and a suction liner contained within the casting area 32 to be described below, application of tension through handle 22 is transferred
30 through a spring 19 located on spring seating 18 to slider rod 26 and to connector 14 which is connected to pin 28 via lock device 16 that is securable to pin 28. Base 12 is axially movable relative to pin 28 so that effectively pin

28, connector 14 and bar 20 are movable axially relative to base 12 under the constraint of the spring 19 on spring seat 18, that reacts the applied tension force into the handle member 22. Expressed differently, axial force applied toward the right in Figs. 1 and 2 through handle 22 is transmitted to a compression spring 19 located on spring seat 18 within the handle 22, which in turn is transmitted to slider bar 20 via the enlarged end of the bar shown to the right in Fig. 2, and then transmitted into the base 14 through the connection between the bar 20 and the base 14. The axial load applied to connector 14 is then transmitted through the lock 16 into the pin 28 to enable the force to be applied to the pin 28 independently of the base 12. The degree to which handle 22 moves relative to the slider bar 20 (i.e., the degree to which spring 19 compresses) may be indicated on a scale 26 engraved or otherwise marked on the forward end (toward the left end as shown) of the outer diameter of bar 20.

Connected to a forward side of the base member 12 is a flexible, expandable annular pressure bladder 34 defining a central casting area 32 and extendable axially forward from the base member 12 over a length of the bladder 34. The bladder 34 is configured and dimensioned to extend generally along the length of a residuum covered by a suction socket on which the prosthesis socket material is to be molded. The bladder 34 preferably includes an outer wall 36 that may be formed of a silicone rubber material reinforced with a web or strands of relatively non-stretchable material or a material that limits extension outwardly of the wall 36 or may be formed of an elastomer material such as silicone elastomer with a separate outer covering of material that limits outward distension of the outer wall 36.

An inner wall 38 of the bladder 34 may be formed of one or more sheets of pliable and compliant sheet material that also may be reinforced with elements that permit tailoring the extensibility of the material according to predetermined criteria. In accordance with the preferred embodiment, the inner wall 38 and outer wall 36 comprises substantially thin, flexible material that permits the bladder 34 to be rolled on and off the residual limb in a similar fashion to the bladder disclosed in U.S. Patent No. 5,885,509 to permit easy

donning and doffing of the bladder 34 over the residual limb. A preferred characteristic of the inner wall 38 of the bladder 34 is that it is formed of a material that will not itself distend substantially when tensioned, yet will be fully compliant when the chamber behind it expands to envelop a residual limb and
5 prosthesis socket molding material that are located within the casting area 32.

In accordance with a preferred embodiment of the invention, the inner wall 38 of bladder 34 is formed from a thin sheet material that is separate from the outer wall 36 and bonded or otherwise attached thereto in a manner defining expandable chambers between the inner wall 38 and the outer wall
10 36. The inner wall 38 may be stitched, heat sealed, bonded or otherwise firmly secured to the inner periphery of the outer wall 36 to define the multiple expandable chambers 40, 42 and 44. The chambers 40, 42 and 44 extend along the length of the bladder 34 and peripherally surround the central casting area 32. The chambers 40, 42 and 44 typically are expandable when
15 pressurized with fluid such as air to cause the inner walls 38 of the chambers to expand inwardly toward the central casting area 32 to exert pressure on a prosthesis socket material to be molded within the bladder 34.

The connector 14, as shown in Fig. 4, includes at least one fluid passage 64 and a pin release mechanism (not shown) for releasing pin 28
20 from the lock device 16 in a manner known in the art. The fluid passage or passages 64 communicates with appropriate ports and conduits in connector 14 and base 12 that are in communication with the interiors of the chambers 40, 42 and 44 to permit pressurized fluid to be supplied to the interiors of the chambers. The fluid passage 64 may be connected with the base 12 instead
25 of the connector 14, if desired. Any other suitable arrangement may be utilized to permit passage of pressurized fluid from a location outside the chambers 40, 42, 44 to the interiors thereof. Indeed, if the option is chosen to utilize the handle 22 as an extension device to apply tractive force to pin 28 which may cause connector 14 to separate from base 12, the fluid passage
30 64 would be oriented and arranged so as to permit continuous supply of pressurized fluid to the interiors of the chambers 40, 42 and 44 while tractive force is applied to pin 28.

The chambers 40, 42 and 44 also could be molded into the sidewall 36, with the inner walls of the sidewall 36 being formed so they are distendable radially inwardly at the inner sides of the chambers 40, 42, 44. In this form, the chambers could be defined by a one-piece sidewall having expandable pockets defining the expandable chambers.

A first embodiment of the bladder 34 is illustrated in Figs. 5A-5D where inner and outer walls 36, 38 define extendable chambers 40, 42 and 44 extending axially along the length of the bladder 34 and circumferentially surrounding the central casting area of 32. The inner wall 38 of the bladder 34 includes non-expandable regions disposed between the chambers 40, 42 and 44 where the inner and outer walls 36, 38 are firmly secured to each other such as by stitching, heat sealing, bonding or the like, such as shown at 39 in Fig. 5D.

The bladder 34 includes a proximal end 35 and a distal end 37, with the proximal end 35 having a smaller diameter than the distal end 37, although the bladder also could be generally cylindrical in form depending on the shape of the socket and the residuum. The length of the bladder 34 is selected so that it will envelop a residuum and prosthesis socket casting material located on the distal end area of the residuum. If desired, a plurality of bladders may be made in several lengths having appropriate minor and major diameters to accommodate various size residuums.

The inner wall 38 is secured to the outer wall 36 along longitudinal seams such as shown at 39 and may be made of a stretchable elastic material or a material that has limited elasticity, provided that the inner wall 38 may distend radially toward the casting area of 32 to a degree sufficient to exert sufficient radial compressive force on casting material located on a residuum that has been placed on the casting area 32. If the inner wall 38 is of limited elasticity, sufficient excess inner wall material will be provided to enable the inside wall to bow inwardly toward the central casting area when the expandable chamber defined by the inner wall is expanded with pressurized fluid.

The arrangement of the inner chambers 40, 42 and 44 can be seen in Figs. 5B, 5C, and 5D.

Fluid passageways 66 may be integrally molded, configured between the walls 36, 38, or otherwise provided in the proximal end structure 35 of the bladder 34, as shown in Figs. 5B and 5C. These passageways communicate with fluid passage or passageways 64 associated with connector 14 or base 12, as previously described. Preferably, each expandable chamber 40, 42 and 44 is provided with an independent fluid passageways 66, although the chambers may be mutually connected if desired so that they will be each exposed to the same internal pressure. Alternatively, the chambers 40, 42 and 44 may be pressurized independently through a series of fluid passageways associated with the connector 14 or the base 12. The passageways may be separate and distinct conduits located inwardly or outwardly of outer wall 36. It is also contemplated that fluid conduits may be incorporated in or through the walls of the bladder 34 directly if desired without passing through the base 12 or connector 14.

When the expandable chambers 40, 42 and 44 are subjected to internal pressurized fluid such as air, they will expand or be driven to the positions shown in hidden lines in Fig. 5D.

Although not illustrated, the chambers 40, 42 and 44 may be subdivided into a plurality of additional connected or independent chambers that may be divided axially along the length of the bladder 34 to provide additional expandable chambers for selectively pressurizing various regions of a residuum and prosthesis casting material during casting of a prosthesis socket using the casting device of this invention.

Also, the expandible chambers could be molded into a single thickness sidewall of the bladder 34, 34' provided that the innermost wall of the chamber is expandable into the casting area.

Figs. 6A-6C illustrate an alternate embodiment of the invention wherein a bladder 34' having proximal and distal ends 35', 37' is generally cylindrical in cross-section and includes an outer wall 36' and an inner wall 38' defining multiple expandable inner chambers 54 and an annular outer chamber 56,

extending over the inner chambers 54 as seen in Fig. 6C. An additional intermediate annular wall 39 spaced inwardly from the outer wall 36' and outwardly of inner wall 38' defines the outer chamber 56 which in this embodiment is similar to the annular pressure chamber described in Patent
5 No. 5,885,509. The side walls 38' and 39 are relatively pliable and compliant to enable the bladder 34' to be easily rolled on or rolled off a residuum and a prosthesis casting material located on the distal end of the residuum so that the casting material may be located within the casting area 32'. The distension characteristics of intermediate wall 39 are selected to distribute
10 desired casting pressure on the residuum and to distribute pressure loading behind the expandable chambers 54. The outer wall 36' also could be provided with a covering or otherwise be constructed so that its distention under internal pressure in the chambers 54, 56 is limited.

A base 12' contains appropriate valving, tubes and conduits enabling
15 distribution of pressurized fluid to the chambers 54 and 56 to enable them to be selectively pressurized independently or collectively to cause inward expansion of the inner walls of the chambers to compress a settable prosthesis socket material in the casting area 32 and 32'. Combination handle and pump 48, 51 is connected to the base 12' through a connector 46 and a
20 pressure indicator 50 may be provided to indicate pressure within the chambers 54, 56. The pump 48, 51 is similar to the pump described in U.S. Patent No. 5,885,509, to which reference may be made for a fuller description of the pump.

Fig. 7 illustrates the embodiment of the casting device illustrated in
25 Figs. 1 and 2 in relation to a residuum 66, a suction socket 62, a molded prosthesis socket S and a locking pin 28 extended from the suction socket 62 through the distal end of the socket S. Fig. 7 depicts the relationship of the depicted elements upon removal of the casting device 10 from the prosthesis socket S after completion of the casting of the socket S and after at least
30 partial curing and hardening of the socket S.

In a manner known in the art, the socket S is then removed from the suction socket 62 for final finishing and the suction sleeve 62 is removed from

the residuum 66. The locking pin 28, of course, may be removed any time by unthreading it from the distal end of the suction sleeve 62.

5 In operation, the residuum is prepared for casting a prosthesis pre-formed casting material, for example as described in U.S. Patent No. 5,718,925, by first placing a suction socket 62 and a locking pin 28 on the distal end of the residuum, which also may be prepared with any other protective layer beneath the suction sleeve.

10 The bladder 34 is unfurled from a folded or retracted position on the base forwardly over the distal end of the residuum 62 with the casting material thereon as described for example in Patent No. 5,885,509. The locking pin 28 may be previously coupled to the base 12 before the bladder is unfurled. The expandable chambers are then pressurized with an appropriate fluid such as air or other medium. The chambers will expand radially inwardly toward the casting area 32, 32' where the prosthesis socket material and residuum are
15 located. The bladder 34, 34' is supported partly at least by the residuum as the inflatable chambers 40, 42 and 44 and chambers 54, 56 are expanded. Prosthetists, if conditions warrant, may impose additional pressure and manipulation in selected locations on the residuum through the bladder and the chambers to control the shape and form of the prosthesis socket material
20 before it is hardened. The prosthesis socket material is selected to be settable or curable into a hardened condition while pressurized by the bladder 34, 34' and its associated expandable chambers. The orientation, location and configuration of the various expandable chambers, 40, 42, 44, 54 and 56 are selected to produce a desirable pressure distribution over the periphery
25 of the prosthesis socket material while it sets into a hardened condition. For example, the use of three peripherally spaced inflatable chambers has been found to produce desirable pressure distributions for casting a prosthesis socket material on a residual limb.

30 As described in Patent No. 5,885,509, anchoring the locking pin 28 relative to the base 12 during casting results in a reactive tractive force being applied to the distal end of a suction socket 62 containing the residuum on which the prosthesis socket material is applied. Such tractive force is highly

desirable and elongates the distal end area of the residuum in a manner resulting in a highly accurate formation of a prosthesis socket internal volume while it is compressed against the residuum. As compared with the single annular expandable chamber used in prior art devices, the multiple
5 expandable chambers distribute casting pressure on the prosthesis socket material in a non-cylindrical pattern that more closely follows the anatomical contours of the typical residuum.

The specific embodiments of the invention described herein are intended to be illustrative only and various modifications thereto may be
10 envisioned and implemented by a person skilled in the art without departing from the spirit and scope of the invention which is defined in the claims that follow.
